findPC: An R package for determining the optimal number of principal components

Haotian Zhuang

2021/9/27

Introduction

findPC is a software tool including multiple metrics to automatically determine the optimal number of principal components to retain based on the standard deviations explained by each PC. A major advantage of findPC is that the only information required is a series of standard deviations explained by each PC.

Installation

findPC software can be installed via Github. Users should have R installed on their computer before installing findPC. R can be downloaded here: http://www.r-project.org/. To install the latest version of findPC package via Github, run following commands in R:

```
if (!require("devtools"))
install.packages("devtools")
devtools::install_github("haotian-zhuang/findPC")
library(findPC)
```

findPC function

```
The synopsis of findPC is:
findPC(sdev,method = 'perpendicular line',aggregate = NULL,figure = FALSE)
```

The default is to return the optimal number of PCs by Perpendicular line. The following codes take the 20PCs of a human tissue (AdultFallopiantube) as an example.

```
## Perpendicular line
## 4
```

The argument 'sdev' should be sorted in decreasing order.

```
findPC(sdev = -sdev)
```

```
## Error in findPC(sdev = -sdev): 'sdev' should be sorted in decreasing order
```

Method

```
The argument 'method' specifies the six methods or returns the six results simultaneously.
findPC(sdev = sdev,method = 'xxx')
## Error in findPC(sdev = sdev, method = "xxx"): 'method' includes 'all', 'piecewise linear model',
       'first derivative', 'second derivative', 'preceding residual',
##
##
       'perpendicular line (default)', 'k-means clustering' options
findPC(sdev = sdev,method = 'all')
                                                       Second derivative
## Piecewise linear model
                                First derivative
##
                                                      K-means clustering
##
       Preceding residual
                               Perpendicular line
##
Method 1: Piecewise linear model
findPC(sdev = sdev,method = 'piecewise linear model')
## Piecewise linear model
##
Method 2: First derivative
findPC(sdev = sdev,method = 'first derivative')
## First derivative
##
Method 3: Second derivative
findPC(sdev = sdev,method = 'second derivative')
## Second derivative
##
Method 4: Preceding residual
findPC(sdev = sdev,method = 'preceding residual')
## Preceding residual
Method 5: Perpendicular line
findPC(sdev = sdev,method = 'perpendicular line')
## Perpendicular line
##
Method 6: K-means clustering
findPC(sdev = sdev,method = 'k-means clustering')
## K-means clustering
##
```

Aggregate

If users are also interested in the mean, median, or voting (median if all are different, otherwise mode) of the results from six methods, the argument 'aggregate' will support them.

```
findPC(sdev = sdev,method = 'all',aggregate = 'mean')

## mean
## 4

findPC(sdev = sdev,method = 'all',aggregate = 'median')

## median
## 4

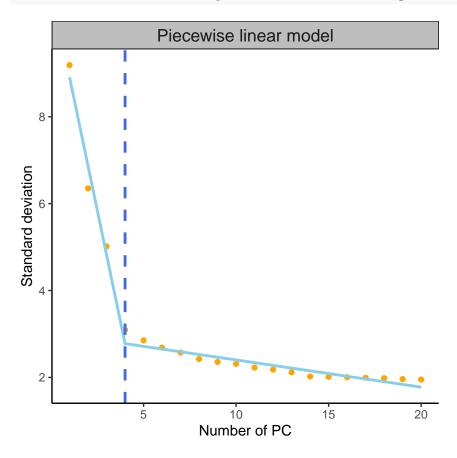

findPC(sdev = sdev,method = 'all',aggregate = 'voting')

## mode
## 4
```

Figure

The last argument 'figure' provides the option to generate informative figures based on each method.

```
findPC(sdev = sdev,method = 'piecewise linear model',figure = TRUE)
```

```
## Piecewise linear model
## 4
```

Figures based on other methods can be generated similarly.

findPC(sdev = sdev,method = 'all',figure = TRUE)
